- **Trademark squatting** describes the
  - ⊕ registration of a trademark on a product, service, or trading name (including commercial and industrial establishments) that is
  - ⊕ marketed by another company that has invested in the goodwill associated with that product, service, or trading name.
- Trademark squatters can be registered companies as well as individuals.
- Squatting **not** necessarily result of (systematic) mistakes by the trademark office

## Let's talk about \$\$\$: anecdotal evidence

- ⊗ *He Doesn't Make Coffee, but He Controls 'Starbucks' in Russia*
  - Sergei A. Zuykov registered trademark for Starbucks in Russia
  - Demanded US\$ 600,000 for re-assignment
  - Claims to successfully squat (e.g. sold 5 trademarks to Audi for US\$ 25,000)
  - Typical price US\$ 30,000 – US\$ 60,000
- ⊗ In Chile practitioners report average price demanded by squatters US\$ 2,000 – US\$ 10,000

## Direct evidence for Chile – reassignment

- ⊕ Direct evidence for successful squatting: trademark ownership transferred from squatter to brandowner

- 71 such trademarks filed by Inmobiliaria e Inversiones Oasis (Jorge Halabi Nacur) between November 2002 and January 2003
- Brandowner **Sisco Textiles** opposes all 71 applications in January/April 2003:

- Opposition to all filings dropped in August 2011
- Trademarks registered in April 2012
- All trademarks re-assigned to **Sisco Textiles**.

# Why Chile?

- **Anecdotal evidence on squatting**
- Trademarks widely used (575,000 filings 1991-2010)
- Trademarks are relatively cheap to register
- No use requirement (though relative grounds examination)
- Chile is not a party to the Madrid system
- Small, remote but fast growing emerging market

# Our research questions

- ① Is there squatting? Is it quantitatively an important phenomenon?
- ② Is there any systematic pattern in squatting behavior?
- ③ What is the effect of squatting on brand owners?
- ④ What features of the legal system favor squatting?

# The economics of squatting

- Squatters obtain rents from
  - ① Selling (licensing) the trademark to the corresponding brand owner
  - ② Using the trademark and the embodied goodwill to market own products
  - ③ Deter product market entry of (foreign) competitors
  - ④ Harm competing importers

# The economics of squatting

- Focus: **selling (licensing) the trademark to the corresponding brand owner**
- 2 risk-neutral agents:
  - ① Agent 1: Brand owner
  - ② Agent 2: Squatter
- Multi-stage game:
  - ① Application phase
  - ② Cancellation-negotiation phase

# The economics of squatting

- Application cost:  $c_i$  for agent  $i = 1, 2$ 
  - $c_1 \geq c_2 > 0$
  
- Probability that trademark is granted:  $\lambda$ 
  - Brand owner:  $\lambda = 1$
  - Squatter:  $\lambda \in (0, 1)$

# Application phase

- **Date 0:** Brand owner decides to file application:
  - *Uncertainty over brand value*
    - Profits of  $i$  depend on brand value
    - Value depends on state of market, which is good or bad.
    - Good with probability  $\mu \in (0, 1)$
    - If good, profits  $h$ , where  $0 < c_1 < h$  and  $\mu h > c_1$
  - *Uncertainty over squatter presence*
    - Squatter present with probability  $\xi \in [0, 1]$
- **Date 1:** If the brand owner has **not** registered the brand, squatter decides to file application
  - Squatter finds out whether state of market good or bad
- **Date 2:** If nobody has registered the brand, the brand owner has a last chance of doing so.
  - Brand owner finds out whether state of market good or bad

# Cancellation-negotiation phase

- Squatter has obtained trademark
- Brand owner has to choose:
  - ① Do nothing:
    - Payoff zero for  $i$
  - ② Request cancellation of the squatted trademark:
    - Payoff for brand owner  $\tilde{h} - k$  with  $\tilde{h} \leq h$
    - Payoff zero for squatter
  - ③ Negotiate with the squatter to buy the squatted trademark:
    - Generalized Nash bargaining game

## Equilibrium without Squatting ( $\xi = 0$ )

- Brand owner:

- Trademark at **Date 0**: *anticipatory value*

$$v_1 = \mu h - c_1 \tag{1}$$

- Trademark at **Date 2**: *value of waiting*

$$w_1 = \mu(h - c_1) \tag{2}$$

- *Net value of waiting*:

$$w_1 - v_1 = (1 - \mu)c_1 > 0 \tag{3}$$

Proposition 1: The brand owner will wait until date 2 to register the brand.

# Equilibrium with Squatting ( $\zeta > 0$ )

- **Cancellation-Negotiation Phase:**

- Squatter has registered trademark
- Assume expensive cancellation:  $\tilde{h} - k \leq 0$ .
- Price  $p$  at which the trademark will be sold to brand owner solves:

$$\max_p (h - p)^{1-\tau} (p)^\tau$$

where  $\tau \in (0, 1)$  is relative bargaining power of squatter.

- Unique price  $p^* = \tau h$
- Payoffs for brand owner and squatter are:

$$n_1^* = h - p^* = (1 - \tau)h, \tag{4}$$

$$n_2^* = p^* = \tau h. \tag{5}$$

# Equilibrium with Squatting ( $\xi > 0$ )

- **The Application Phase:**

- *Squatter*: at date 1 if state is good payoff:

$$\pi_2^* = \lambda \tau h - c_2 \tag{6}$$

- *Brand owner*: payoff  $h - c_1$  if brand registered at date 2 which happens with probability:

$$\mu \xi (1 - \lambda) + \mu (1 - \xi)$$

- *Brand owner*: payoff  $n_1^*$  when a squatter registers the trademark application, which happens with probability:

$$\mu \xi \lambda$$

- Value of waiting in presence of squatting:

$$w_1^* = w_1 - \underbrace{\mu \lambda \xi (\tau h - c_1)}_{\text{Squatting Tax}} \tag{7}$$

## Equilibrium with Squatting ( $\xi > 0$ )

- *Squatting active equilibrium:*

- a. Brand owner waits up to date 2 to register brand iff cost (weakly) higher than  $c_1^*$ , the *smallest* possible cost that makes the net value of waiting positive:

$$c_1 \geq c_1^* \equiv \frac{\mu\lambda\xi}{\mu\lambda\xi + (1-\mu)}\tau h \quad (8)$$

- b. Squatter, after observing good state, files trademark application iff cost (weakly) smaller than  $c_2^*$ , the *largest* possible cost that makes squatting profitable:

$$c_2 \leq c_2^* \equiv \lambda\tau h \quad (9)$$

Proposition 2: A squatting active equilibrium exists if, and only if:

- a.  $c_2 \leq c_2^* \leq c_1^* \leq c_1$ ; or:

- b.  $c_1^* \leq c_2 \leq c_1 \leq c_2^*$ ,

holds.

# The economics of squatting: equilibria

Proposition 3: If:

- a.  $0 < c < c_1^*$ , there is a unique pre-emptive equilibrium;
- b.  $c_1^* \leq c \leq c_2^*$ , there is a unique squatting active equilibrium;
- c.  $c_2^* < c$ , there is a unique squatting free equilibrium.

# The economics of squatting: equilibria

Proposition 3: If:

- a.  $0 < c < c_1^*$ , there is a unique pre-emptive equilibrium;
- b.  $c_1^* \leq c \leq c_2^*$ , **there is a unique squatting active equilibrium;**
- c.  $c_2^* < c$ , there is a unique squatting free equilibrium.

# The Chilean trademark system

- Trademarks in either product or service classes (1991-2010)
- Application fee is around USD\$ 85 per class
- Opposition within 30 days following publication (fee USD\$ 113)
- Relative grounds examination
- Registration fee of USD\$170
- No legal requirement for demonstrating (any intent to) use of a trademark

- All trademark filings by residents and non-residents with INAPI 1991-2010 (575,000 filings)
- Identification of unique applicant
- Detailed legal status information
- Digitization of opposition information
- Digitization of cancelation information

# Identifying squatters: criteria

- 1 Applicant type: companies and individuals
- 2 Rejected applications ratio
- 3 Opposition ratio
- 4 Revocation ratio
- 5 Simultaneous filings
- 6 Diversity of Nice classes
- 7 Priority
- 8 Trademark use
- 9 Products vs services
- 10 Well-known brands

Companies and individuals  $\geq 2$  trademarks

## Descriptive evidence: registered TMs

# Descriptive evidence: economic activities

# The effect of squatters on brand owners – **opposition**

- ⊕ Filing behavior of brand owners after having opposed a squatter application **for the first time**:
  - Event study

$$tm_{i\tau} = \alpha + \beta_s O_{i\tau=0} \times SQ_i + \beta_o O_{i\tau=0} + X_{i\tau} + \mu_i + \theta_\tau + \varepsilon_{i\tau}$$

where  $tm_{i\tau}$  filings by brand owner  $i$  in  $\tau$  (including brand owners opposing a squatted trademark filing as well as brand owners opposing a filing by a 'legitimate' applicant),  $\mu_i$  applicant-level fixed effects,  $\theta_\tau$  time trend,  $X_{i\tau}$  applicant-level controls.  $O_{i\tau=0}$  dummy variably equal to one once a brand owner opposed *for the first time* a trademark.

# Example: The NBA's response to squatting

# Opposition event study: $-/+24$ months after 1st opposition:

$$tm_{i\tau} = \alpha + \sum_{\tau=-24}^{-24} \beta_s O_{i\tau=0} \times SQ_i + \mu_i + \theta_\tau + \varepsilon_{i\tau}$$
